

Exotic Pets Reviews: More Information on Alligators and Crocodile

There are many features of alligators that distinguish them from crocodiles and both of them belong to different taxonomic families. Alligators have a broader snout and their eyes are located near the upper side. When light is flashed over the eyes, bigger alligators have a red glow and smaller alligators have a green glow. This can be of help, when searching for alligators in dark. When looking in daylight, it is also observed that alligators have brown eyes and crocodiles have green eyes.

Alligators can eat anything they can find because of the gastroliths (stomach stones) present in their stomach. Young alligators feed on crustaceans, fishes, snails, and insects. As they grow so does their need for larger prey. Bigger alligators feed on turtles, bigger fishes, birds, and, other reptiles and mammals. They even eat deer, razorbacks, small alligators and carcass of animals when they are extremely hungry. Few attacks on humans have also been reported, but the number is on the rise. People get overconfident about this fact and enter alligator habitats without much care, resulting in provoking their aggression. But alligators do not immediately attack humans, like crocodiles.

Alligators are bound to get aggressive and dangerous at times, which can prove fatal to people around. Owners should be prepared as their pet can grow more than twelve feet. Some owners panic when they start getting bigger and longer and decide to free it from the captivity. But this can be extremely dangerous to residents of that locality because by then the animal would lose its natural fear and will attack humans. When decision is taken for adopting an alligator as a pet, the owner should be firm enough to make a lifetime commitment.

Crocodiles

These reptiles are often underestimated, but they are very strong and fast. Lots of practice should be done before handling a crocodile. In fact, the larger the crocodile, the more the number of people required for handling it. If untrained or inexperienced team handles a crocodile, they are prone to getting serious injuries and might even die on the spot. No amount of training can tame the crocodile. Most of the owners are in delusion in this regard. A lot of hard work and many years of time would have to be invested to tame a crocodile.

Crocodiles have a streamline body, which facilitates swimming. While swimming, they tuck their limbs to the side of their bodies, which help them to swim even faster as that decreases the water resistance. Their webbed feet help them to make fast and sudden turns. Muscles that are involved in closing the jaw are so powerful that the jaw can shut with a pressure of three thousand pounds per square inch. Their teeth are very sharp which they use to tear flesh of their prey. They also have very sharp claws.
